

```

@Test
public void mogrifyTest() {
    assertEquals("mogrify fails",
        new int[] { 2, 4, 8,
12 },
        MyClass.mogrify(new
int[] { 1, 2, 4, 6 }));
}

```

The test always seems to fail, no matter what mogrify does. Why?

- A student sees this in an autograder log:

Fatal: no proj0/signpost directory.

What is likely to be the problem?

- A student does not see his proj0 submission under the Scores tab. What can be the problem?

allows implementer of a class to control all manipulation of objects of that class.

- In particular, this means that Java gives the constructor of a class the first shot at each new object.
- When one class extends another, there are two constructors—one for the parent type and one for the new (child) type.
- In this case, Java guarantees that one of the parent's constructors is called first. In effect, there is a call to a parent constructor at the beginning of every one of the child's constructors.
- You can call the parent's constructor yourself. By default, Java calls the "default" (parameterless) constructor.

```

class Figure {
    extends Figure {
class Rectangle

```

defined by a superclass's method, rather than to completely override it.

- The overriding method can refer to overridden methods by using the special prefix `super`.
- For example, you have a class with expensive functions, and you'd like a memoizing version of the class.

```

class ComputeHard {
    int cogitate(String x, int y) { ... }
}

class ComputeLazily extends ComputeHard {
    int cogitate(String x, int y) {
        if (don't already have answer for this x and
y) {
            int result = super.cogitate(x, y); //
<<< Calls overridden function
memoize (save) result;

```

to extend something.

- Homework gives example of a `TrReader`, which *contains* another `Reader`, to which it *delegates* the task of actually going out and reading characters.
- Another example: a class that instruments objects:

```
interface Storage {
    void put(Object x);
    Object get();
}

class Monitor implements Storage {
    int gets, puts;
    private Storage store;
    Monitor(Storage x) { store = x; gets = puts = 0; }
    public void put(Object x) { puts += 1; store.put(x); }
    public Object get() { gets += 1; return store.get(); }
}
```

CS61B: Lecture #12 7

```
1(s);
1(s);
System.out.println(S.gets + "
gets");
```

Monitor is called a *wrapper class*.

CS61B: Lecture #12 8

voted to detecting and responding to errors.

- Some errors are external (bad input, network failures); others are internal errors in programs.
- When method has stated precondition, it's the client's job to comply.
- Still, it's nice to detect and report client's errors.
- In Java, we *throw exception objects*, typically:

```
throw new SomeException (optional description);
```

- Exceptions are objects. By convention, they are given two constructors: one with no arguments, and one with a descriptive string argument (which the exception stores).

CS61B: Lecture #12 9

terminate abruptly, until (and unless) we come to a `try` block.

- Catch exceptions and do something corrective with `try`:

```
try {
    Stuff that might throw exception;
} catch (SomeException e) {
    Do something reasonable;
} catch (SomeOtherException e) {
    Do something else reasonable;
}
Go on with life;
```

- When `SomeException` exception occurs during "Stuff..." and is not handled there, we immediately "do something reasonable" and then "go on with life."
- Descriptive string (if any) available as `e.getMessage()` for error messages and the like.

CS61B: Lecture #12 11

A `catch` clause will catch any subtype of that exception as well:

```
try {
    Code that might throw a FileNotFoundException or a
    MalformedURLException ;
} catch (IOException ex) {
    Handle any kind of IOException;
}
```

- Since `FileNotFoundException` and `MalformedURLException` both inherit from `IOException`, the `catch` handles both cases.
- Subtyping means that multiple `catch` clauses can apply; Java takes the first.
- Stylistically, it's nice to be more (concrete) about exception types where possible.
- In particular, our style checker will therefore balk at the use of `Exception`, `RuntimeException`,

Last modified: Wed Sep 25 19:36:30 2019

CS61B: Lecture #12 12

Using multiple exceptions the same way:

```
try {
    Code that might throw IllegalArgumentException
    or IllegalStateException;
} catch (IllegalArgumentException | IllegalStateException
ex) {
    Handle exception;
}
```

be a subtype of `Throwable` (in `java.lang`).

- Java pre-declares several such subtypes, among them
 - `Error`, used for serious, unrecoverable errors;
 - `Exception`, intended for all other exceptions;
 - `RuntimeException`, a subtype of `Exception` intended mostly for programming errors too common to be worth declaring.
- Pre-declared exceptions are all subtypes of one of these.
- Any subtype of `Error` or `RuntimeException` is said to be *unchecked*.
- All other exception types are *checked*.

- Programmer errors: many library functions throw `IllegalArgumentException` when one fails to meet a precondition.
- Errors detected by the basic Java system: e.g.,
 - * Executing `x.y` when `x` is null,
 - * Executing `A[i]` when `i` is out of bounds,
 - * Executing `(String) x` when `x` turns out not to point to a `String`.
- Certain catastrophic failures, such as running out of memory.
- May be thrown anywhere at any time with no special preparation.

that are not necessarily programmer errors.
Examples:

- Attempting to open a file that does not exist.
- Input or output errors on a file.
- Receiving an interrupt.
- Every checked exception that can occur inside a method must either be handled by a `try` statement, or reported in the method's declaration.
- For example,

```
void myRead() throws IOException, InterruptedException
{ ... }
```

means that `myRead` (or something it calls) *might* throw `IOException` or `InterruptedException`.
- Language Design: Why did Java make the following illegal?

```
}
}
```

statements and `System.exit` everywhere,

- ...because response to a problem may depend on the *caller*, not just method where problem arises.
- Nice to throw an exception when programmer violates preconditions.
- Particularly good idea to throw an exception rather than let bad input corrupt a data structure.
- Good idea to document when methods throw exceptions.
- To convey information about the cause of exceptional condition, put it into the exception rather than into some global variable:

```
class MyBad extends Exception {           try {...  
    public IntList errs;                  } catch  
(MyBad e) {
```
