"An engineer is someone who can do for a dime what any fool can do for a dollar." • Cost can mean - Operational cost (for programs, time to run, space requirements). - Development costs: How much engineering time? When delivered? - Maintenance costs: Upgrades, bug fixes. - Costs of failure: How robust? How safe? • Is this program fast enough? Depends on: - For what purpose; - For what input data. • How much space (memory, disk space)? - Again depends on what input data.

	less to be precise about certain things: - Behavior on small inputs: * Can always pre-calculate some results. * Times for small inputs not usually important. * Often more interested in asymptotic behavior as input size becomes very large. - Constant factors (as in "off by factor of 2"): * Just changing machines causes constant-factor change. • How to abstract away from (i.e., ignore) these things?
Last modified: Sun Oct 6 13:57:15 2019 CS61B: Lecture #16 7	Last modified: Sun Oct 6 13:57:15 2019 CS61B: Lecture #16 8
tions that specity size, but rather tamilles	of functions bracketed in magnitude by two
of functions with similarly behaved magnitudes. • Then say something like " f is bounded by g if it is in g 's family." • For any function $g(x)$, the functions $2g(x)$, $0.5g(x)$, or for any $K>0$, $K\cdot g(x)$, all have the same "shape". So put all of them into g 's family. • Any function $h(x)$ such that $h(x) = K\cdot g(x)$ for $x>M$ (for some constant M) has g 's shape "except for small values." So put all of these in g 's family. • For upper limits, throw in all functions whose absolute value is everywhere \leq some member of g 's family. Call this set $O(g)$ or $O(g(n))$. • Or, for lower limits, throw in all functions	members of g 's family. Last modified: Sun Oct 6 13:57:15 2019 CS618: Lecture #16 10
$M=1$ $f(x)$ $g(x)$ $\bullet \text{ Here, } f(x) \leq 2g(x) \text{ as long as } x>1,$ $\bullet \text{ So } f(x) \text{ is in } g\text{'s "bounded-above family," written}$ $f(x) \in O(g(x)),$ $\bullet \dots \text{ even though (in this case) } f(x) > g(x) \text{ everywhere.}$	$M=1 \qquad g(x)$ $f'(x)$ $0.5g(x)$ $\bullet \text{ Here, } f'(x) \geq \frac{1}{2}g(x) \text{ as long as } x>1,$ $\bullet \text{ So } f'(x) \text{ is in } g\text{'s "bounded-below family," written}$ $f'(x) \in \Omega(g(x)),$ $\bullet \dots \text{ even though } f(x) < g(x) \text{ everywhere.}$

of the cost function.

• Since we are approximating anyway, point-

approximate, may tell very little about actual time.

 $f(x) \in O(g(x))$ and $f'(x) \in \Omega(g(x))_{\mu \dots}$

- ullet ... but also $f(x) \in \Omega(g(x))$ and $f'(x) \in O(g(x))$.
- We can summarize this all by saying $f(x) \in \Theta(g(x))$ and $f'(x) \in \Theta(g(x))$.

ullet Technically, if I am going to talk about $O(\cdot)$, $\Omega(\cdot)$ and $\Theta(\cdot)$ as sets of functions, I really should write, for example,

 $f \in O(g)$ instead of $f(x) \in O(g(x))$

- \bullet In effect, $f(x) \in O(g(x))$ is short for $\lambda\,x.\,f(x) \in O(\lambda\,x.\,g(x)).$
- \bullet The standard notation outside this course, in fact, is f(x)=O(g(x)), but personally, I think that's a serious abuse of notation.

CS61B: Lecture #16 14

etc., usea generally to specity bounds on tunctions.

• For example,

$$\pi(N) = \Theta(\frac{N}{\ln N})$$

which I would prefer to write

$$\pi(N) \in \Theta(\frac{N}{\ln N})$$

(Here, $\pi(N)$ is the number of primes less than or equal to N.)

• Also, you'll see things like

$$f(x)=x^3+x^2+O(x) \quad \text{(or } f(x)\in x^4+x^2+O(x)\text{),}$$
 meaning that $f(x)=x^3+x^2+g(x)$ where $g(x)\in O(x).$

• For our purposes, the functions we will be bounding will be cost functions: functions

```
real-valued tunction.
```

• We will use them to describe cost functions. Example:

```
/** Find position of X in list L, or
-1 if not found. */
  int find(List L, Object X) {
     int c;
     for (c = 0; L != null; L = L.next,
c += 1)
        if (X.equals(L.head)) return c;
     return -1;
  }
```

- Choose representative operation: number of .equals tests.
- ullet If N is length of L, then loop does at most N tests: worst-case time is N tests.
- In fact, total # of instructions executed is Last modified: Sun Oct 6 13:57:15 2019 CS61B: Lecture #16 19

ullet Use N>M provision (in defn. of $O(\cdot)$) to ignore empty list.

CS61B: Lecture #16 20

 $O(N^2)$, since $N \in O(N^2)$ also: Big-On bounds are loose.

- ullet The worst-case time is $\Omega(N)$, since $N\in\Omega(N)$, but that does not mean that the loop always takes time N, or even $K \cdot N$ for some K.
- Instead, we are just saying something about the function that maps N into the largest possible time required to process any array of length N.
- To say as much as possible about our worstcase time, we should try to give a Θ bound: in this case, we can: $\Theta(N)$.
- But again, that still tells us nothing about best-case time, which happens when we find X at the beginning of the loop. Best-case time is $\Theta(1)$.

Last modified: Sun Oct 6 13:57:15 2019

CS61B: Lecture #16 21

CS61B: Lecture #16 23

```
for (int i = 0; i < A.length; i += 1)
   for (int j = 0; j < A.length; j +=
      if (i != j && A[i] == A[j])
        return true;
return false;
```

- ullet Clearly, time is $O(N^2)$, where $N={\tt A.length}.$ Worst-case time is $\Theta(N^2)$.
- Loop is inefficient though:

```
for (int i = 0; i < A.length; i += 1)</pre>
  for (int j = i+1; j < A.length; j
      if (A[i] == A[j]) return true;
return false;
```

• Now worst-case time is proportional to

CS61B: Lecture #16 22

```
    Silly example of recursion. In the worst

 case, both recursive calls happen:
```

```
/** True iff X is a substring of S */
boolean occurs(String S, String X) {
  if (S.equals(X)) return true;
  if (S.length() <= X.length()) return false;</pre>
  return
    occurs(S.substring(1), X) ||
    occurs(S.substring(0, S.length()-1), X);
```

ullet Define C(N) to be the worst-case cost of occurs(S,X) for S of length N, X of fixed size N_0 , measured in # of calls to occurs.

$$C(N) = \left\{ \begin{array}{ll} 1, & \text{if } N \leq N_0 \text{,} \\ 2C(N-1) + 1 & \text{if } N > N_0 \end{array} \right. \label{eq:constraint}$$

ullet So C(N) grows exponentially:

$$C(N) \ = \ 2C(N-1) + 1 = 2(2C(N-2) + 1) + 1 = \ldots = \underbrace{2(\cdots 2}_{N-N-1} \cdot 1 + 1) + \ldots$$
